- Many flavors of Unix, some for the PC platform, including many distributions Linux.
 - Collectively, they will be referred to as **nix*
- Where there's a difference, these notes discuss Linux, and many of the utilities from the gnome toolkit
- So, on some other **nix* platforms, you might notice slightly different behavior, maybe some missing options, some other small differences
 - E.g., emacs is the default Linux editor, rather than vim
 - Linux pushes `info` pages (but still has `man`)

Flavors of Unix

There are many flavors of Unix used by many people. This is *not* a complete listing:

- SysV (from AT&T)
- BSD (from Berkeley)
- Solaris (Sun)
- IRIX (SGI)
- AIX (IBM)
- OSF1 (DEC)
- Linux (free software)
 - Thank Linus Torvalds

*nix and Users

Editors

- Most flavors of *nix provide the same set of applications and services (commands, shells)
- Although these programs are not directly part of the OS, they are standardised enough that learning your way around one flavor of *nix is sufficient
- Unix got its start in the early 70s
- Was used (and grown) by engineering and science types

Notes for Mac OS X Users

- Since OS X, Mac runs on BSD Unix
- You can get many of the gnome command-line utilities discussed here just by installing XTools
- Or, Homebrew, a package manager for MacOS, provides access to coreutils, and other gnu utilities
 - Installed separately, can be made default
- You can simply open a terminal window, `ssh` to the department machines, and work there

Notes for Windows Users

- Cygwin – A *nix-like subsystem, runs on top of Windows
 - Try MobaXTerm. Very nice front-end to cygwin, with an X-Server
- Linux Bash Shell on Windows 10 – User space and bash shell, running natively on Windows¹
- You can install some flavor of Linux on a partition of your disk
- Or, run Linux inside a Virtual Machine

¹I'm not in love w/it

Objective: Introduce students to the features of *nix, and the Unix Philosophy (a collection of combinable tools and environments that support their use)

- Basic commands
- File system
- Shell
- Filters (more, grep, sort, wc)
- Pipes, file redirection

Operating Systems

An *Operating System* controls (manages) hardware and software

- Provides support for peripherals such as keyboard, mouse, screen, disk drives, etc.
- The OS typically manages (starts, stops, schedules, etc.) applications
- Software applications use the OS to communicate with peripherals (screen, networking, etc), and with other applications

Kernel (OS)

Unix -

- Interacts directly with the hardware through device drivers
- Provides sets of services to programs, insulating these programs from the underlying hardware
- Manages memory, controls access, maintains filesystem, handles interrupts, allocates resources of the computer

The Shell

Unix -

You can:

- Sit at the *console* (the computer itself)¹
- Connect from any remote computer connected by a network, via SSH, e.g.
- Remember, usernames and passwords are case sensitive!

¹Note, if you sit at any of the department Linux machines, your home directory will be mounted there. You shouldn't notice a difference

Incorrect Login

- From a *nix machine, or a Mac, just open terminal, use `ssh`
- Windows doesn't have SSH built in
 - Any SSH client would do
 - I recommend PuTTY
 - Windows 10 is supposed to have the SSH stack, but I've not seen it yet
- To avoid always typing your password, search the Web for `ssh-keygen`
- **Keep your passwords and keys safe!**

Typically (or, on tux, anyway):

- A sequence of alphanumeric characters (there might be some others)
- Length no more than 8
- The primary identifying attribute of your account
- Unique (so, typically how I know and refer to you)
- Used as your email address
- The name of your home directory is related
 - On the CS machines, if your ID is abc123, then your home directory is /home/abc123

- A secret string, not even the system knows
 - System hashes (encrypts) the password, compares it to the stored hash
- Should have at least 6 characters
- Should contain upper- and lower-case letters, numbers, and even other characters
- Don't use anything that appears in any dictionary
- Don't use anything that can be gleaned from your past, or your current likes
- Consider a line in a song, or poem. Use the first letter of each word

- A *file* is a basic unit of storage (e.g., the disk)
- Every file has name
- Filenames are case sensitive
- Unix filenames can contain any character except the slash (/) and the null character
 - Some characters, like shell metacharacters, make it more difficult to refer to the file

File Names

Editors

- Every file has at least one name
 - See `ln`, inodes
- Each file *in the same directory* must have a unique name
- Files in different directories can have identical names
- Files that start with a `.` are, by default, hidden by `ls`, and other utilities

Directories

- Sometimes called a *folder*
- A *directory* is a special sort of file
 - holds information about other files
- Container for other files (including directories)
- Other file types include *symbolic links* (just like shortcuts), *named pipes*, *block special files* (disks, USB drives)

Unix Filesystem

Editors

- A hierarchical system of organising files and directories
- The top level in the hierarchy is called the *root*
 - Holds *all* files and directories in the filesystem
 - Its name is /
- Filesystem may span many disks, even across a network

Filesystem – eg.

Pathnames

Unix -
Introduction

Quoting, Escaping

I/O Redirection

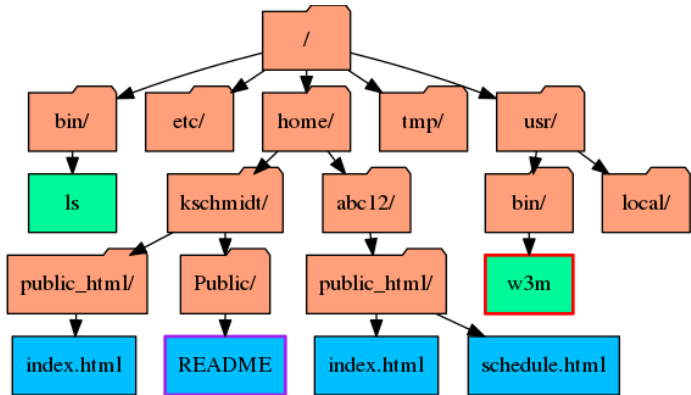

Pipes

Processes,
Jobs

Editors

- The *pathname* of a file includes the name of the file, the directory that holds the file, the directory that holds *that* directory... up to the root
- The pathname of every file in a given filesystem is unique
- Absolute pathnames start at the root, drill down through successive subdirectories
- The forward slash, /, separates path components
 - So, can't be used in a filename
 - The only other character is \0, the null-terminating character

Pathnames – eg.

■ `/usr/bin/w3m`

■ `/home/kschmidt/Public/README`

Absolute Pathnames

Metacharacters

Parameters

Command
Substitution

Quoting, Escaping

I/O Redirection

Pipes

Processes,
Jobs

Editors

- The pathnames, above, are *absolute* pathnames
- Start at the root
- Uniquely identify files
- There are 2 absolute paths that don't, apparently, start at the root:
 - `~kschmidt/` \Leftrightarrow `/home/kschmidt` (to refer to any user's home directory)
 - `~/` – **Your** home directory. So, relative to login, `$USER`

Relative Pathnames

Unix -

Editors

- `.` – the *current* directory
- `..` – the *parent* directory

```
$ cd ~abc12
$ pwd
/home/abc12
$ ls -F ../kschmidt/
public_html/ Public/
$ cp ../kschmidt/Public/README . # copy that file here
```

Filesystem v. Disk

- The hierarchy can actually span parts of many disk drives (partitions)
- Even partitions on other computers

Bash is the default shell, and the one we'll discuss here

- Tokens are separated by whitespace
- Shell expects the first token to be a command¹
- All subsequent tokens are arguments
- Arguments that start with a dash, `-`, or two dashes, are called *options* (generally, Posixly)
 - Used to modify the behavior of the command
 - Note, not all utilities are Posix compliant (e.g, `tar`)
- Non-option arguments are data passed to the command

¹ Commands may be preceded by a sequence of variable assignments 

Command Syntax

Editors

```
ls -a -l Labs/Unix Lectures
```

- `ls` – utility, to list contents of a directory
- `-a` – option, to include hidden files (all)
- `-l` – option, spit out long listing
- `Labs/Unix` – argument, directory to list
- `Lectures` – argument, another directory to list

Note, short options which don't require arguments (*optargs*) can generally be stacked:

```
ls -al Labs/Unix Lectures
```

Options, Optargs

Editors

Options come in 2 flavors:

- *Toggles*, or flags. On or off
- Options which, in turn, need information

```
tail -f -n30 error.log
```

- `-f` – A toggle, tells `tail` to update (follow)
- `-n 30` – Tells `tail` to display 30 lines

Traversing the Filesystem

Editors

- `ls` – lists file or contents of a directory (current directory by default)
 - `-a` – show hidden files (all)
 - `-o`, `-l` – long (and longer) listing
 - `-d` – directory (don't list out the contents)
 - `-F` – Decorate names depending on filetype
- `pwd` – print the working (current) directory
- `cd` – change directory¹
 - By default, takes you home

¹Also see Bash's `pushd` and `popd`

Getting Help – man, info

Man Pages:

`man ls`

- Get information on any properly installed utility (`ls`, `grep`, etc.)
- Can do a keyword search: `man -k music`
- Split into sections (note them)
- Flat, unexciting, but very useful

Info pages are often provided

- Hierarchical; not flat
- Navigation uses emacs-like bindings
- If no info page, it'll display the man page

Viewing Text Files

Pipes

Processes,
Jobs

Editors

- `rm` – *remove* file
 - `-r` – *recursive*. Careful, here
 - `-f` – *force*. Ignore nonexistent files
- `cp` – *copy*
 - `-i` – *interactive*. Ask before overwriting destination file (if it exists)
- `mv` – *move*. Also, rename, you can give the file a different name as you move it
 - `-i` – *interactive*. Ask before overwriting destination file (if it exists)

Directories

Pipes

Processes,
Jobs

Editors

- `mkdir` — *make directory*
- `rmdir` — *remove directory*
 - Safe; it won't remove non-empty directories
 - Compare to `rm -rf` (and be careful)
- Directories can be moved/renamed using `mv`
- Entire directories can be copied using `cp -r`
 - See `rsync`

Archiving

Quoting, Escaping

I/O Redirection

Pipes

Processes,
Jobs

Editors

- `tar` – *tape archive*
 - makes one large file from many smaller files
- `gzip`, `gunzip` – One (of many) compression utilities
 - `bzip2` `compress` `xz` `zcat` `zip`
- `tar` on Linux does `gzip` compression (and others) using the `z` option:

```
tar czf 571back.tgz CS571
tar xzf assn1.tgz # or .tar.gz
```

Filters

Editors

Programs that read some input, perform some transformation, write out the results

- `head`, `tail` – Displays first (last) *n* lines of input
- `grep` – Search input using *regular expressions*
- `sort` – Sorts input by lines (lexically, or numerically)
- `uniq` – *Unique*, removes identical, adjacent lines
- `wc` – *Word count* (line count, character count)
- `cut` – Select fields of a line
- `tr` – *Translate*

- Each file has a set of permissions that controls who can do what to the file
 - Note, ACLs are newer, ride on top of these permissions
- There are three types of permissions
 - `r` – read
 - `w` – write
 - `x` – execute
- Permissions are set for these entities
 - user (the file's owner)
 - group (members of the file's group)
 - other (world; everybody else)

`-rw-rw-r--`

- – Plain file

d – Directory

l – Symbolic link

p – Named pipe

c – Character file
(keyboard,
mouse, etc.)

b – Block (disk
drives, USB,
etc.)

user's permissions

group's permissions

others' permissions

Files:

- **r** – allowed to read
- **w** – allowed to write
- **x** – allowed to execute

Directories:

- **r** – Can list out the directory (view contents)
- **w** – allowed to create and remove files
- **x** – allowed to "enter" the directory, change to subdirectories, edit files

`chmod mode(s) file(s)`

- `chmod` command changes permissions on a file or directory
- Modes can be expressed symbolically, or as octal values

```
chmod 755 Public # Typical perms for a public directory or executable
chmod 644 README # Typical perms for a public file
chmod a+x script # Add execute permissions for everybody
```

- `-R` – `chmod` goes recursive
 - See `+X`

Consider each set of permission bits as a 3-digit binary number:

■ $r - 4$

■ $w - 2$

■ $x - 1$

A permission (mode) for all three sets is a 3-digit octal number:

■ $755 - rwxr-xr-x$

■ $640 - rw-r-----$

■ $711 - rwx--x--x$

- A shell is a command interpreter
- Interface between a human (or another program) and the OS
 - Runs a program (say, `ls`, or a Solitaire game or Web browser)
 - Can establish alternative sources of input and destinations for output of programs
- Is, itself, just another program

Has features commonly found in languages for structured programs

- Allow shell scripts to be used as filters
- Control flow, variables
- Control over all I/O file descriptors
- Control over signal handling
- The environment allows context to be established at startup
 - Provides a way for scripts to pass information to processes w/out using positional parameters

Bourne Again Shell (`bash`)

- The `set` builtin with no args displays all shell variables and functions
- Can be used to set various options. E.g.,
 - `-o noclobber` – Won't let re-direct overwrite an existing file
 - `-o ignoreeof` – Shell won't exit on `^D`
 - `-o vi` – Use vi-like keybindings for editing the command line. `emacs` is the default
 - `-n` – Dry run. Just parse, but don't execute. Handy for debugging scripts
 - `-x` – Echo on. Shows commands in script as they execute

Interpreting Commands

Editors

- A *shell builtin* is a command the shell will do for you
 - `cd`, `type`, `pushd`, `set`, `pwd`, ...
- They are faster
- The shell provides builtins for some common disk utilities
 - `echo`, `printf`, `test`
 - Use a path to invoke the disk utility (`/bin/echo`)
- The builtin `type` will determine if a command is a builtin, or tell you where the utility is on disk
- The `help` builtin will give you help on any builtin, or show you all of the the shell builtins

- Disk programs are run in a subshell
- The subshell *execs* the program
 - Replaces itself with the program
- If the command isn't a shell builtin, the shell will search for a disk utility (using your \$PATH)
- If the command token contains a path, then that utility will simply be run

```
$ /usr/bin/firefox & # kick firefox off in the background
$ /usr/bin/python myScript.py # invoke the python interpreter
$ ~/bin/cow-sample # Invoke my script to see cows
$ ./a.out # run a program I just compiled, in this directory
```

- `stdin` is read like any other file¹
- If `stdin` is the keyboard, use Ctrl-D (`^D`) to signal EOF
- Many utilities, filters, will read `stdin` if not given a filename(s) to open
 - `cat head grep awk sort ...`
- If it appears a program “isn’t doing anything”, it’s possible that it’s waiting on you

```
$ grep the # no filename
What's this?
Is this the line?
Is this the line?
That's not funny.
Maybe there should be a law
Maybe there should be a law
^D # ctrl-D, EOF
```

¹Sorta. You can't back up

Shell Metacharacters

Unix -
Introduction
Kurt Schmidt

A *metacharacter* is a character which has special meaning to the shell

Here are *some*:

- Wildcards

* ? []

- I/O redirection

< > |

- Others

& ; \$ # ! \ () " ' ,

These characters must be escaped or quoted to inhibit their special behavior

```
$ ls "some file" another\&file 'and;yet;a;third'  
some file another&file and;yet;a;third
```

Wildcards

Also known as *name globbing* and *pattern matching*; used in *filename expansion*

- * – matches 0 or more characters
- ? – matches exactly 1 character
- [list] – matches any single character from *list*
- Wildcards are *not* regular expressions

`ls *.cc` list all C++ source files in directory

`ls ?a*` list all files whose 2nd letter is 'a'

`ls [a-cf]*.jpeg` list all JPEGs that start with a, b, c, or f

`ls [!ac-e]*.jpeg` list all JPEGs that do *not* start with a, c, d, e

`ls *` Try it with non-empty subdirectories present

Shell Variables

Called *parameters*

- Bash uses shell variables to store information
- Used to affect the behavior of the shell, and other programs
- Simple mechanism, just stores text
- Bash does have arrays and associative arrays (see `declare builtin`)

Editors

- Replaces the command with the output of the command

```
$( cmd )
```

```
$ echo Today is $(date '+%d %B' )  
04 October
```

- Command can also be enclosed in back-tics, ‘

```
‘ cmd ‘
```

```
$ echo Today is ‘date '+%d %B'’  
04 October
```

- This is Bourne syntax
- Tougher on the eyeballs

\ – The Escape Character

Use the backslash to inhibit the special meaning (behavior) of the metacharacter that follows.

```
$ echo $USER  
kschmidt  
$ echo \ $USER  
$USER
```

So, now \ is a metacharacter. Escape it to get just the character:

```
$ echo a\\b  
a\b
```

\ Followed by Newline

The backslash, when followed immediately by a newline, effectively removes the newline from the stream

```
$ echo On the bloody morning after\  
> One tin soldier rides away  
On the bloody morning afterOne tin soldier rides away
```

Use quotes, if you want the newline in the output:

```
$ echo "On the bloody morning after  
> One tin soldier rides away"  
On the bloody morning after  
One tin soldier rides away
```

The shell can read `stdin` from sources other than your keyboard

- Input can be redirected from a file
- Input can even be taken from the output of another process, though a *pipe*

Similarly, `stdout` (and `stderr`) can go places other than your screen

- Redirected to a file
- Piped to another process to read as input

Redirecting stdout

Editors

- stdout is file descriptor 1
- Use `>` after a command (and its arguments) to redirect the output to a file:

```
$ ls > list.out
```

- If `list.out` previously existed it will be truncated (gone)
- Use `>>` to append the output to the file.

```
$ ls >> list.out
```

Editors

- echo (builtin, and disk utility) writes a line to stdout
 - -n suppresses the newline
 - -e permits expansion of escape chars (\t, \n, etc.)
- The printf utility is handy for formatting output

```
$ idx=127
$ echo "First line" > "$logfile"
$ echo "Another line" >> "$logfile"
$ printf '%-15s formatted line %5x\n' "$USER" $idx >> "$logfile"
$ cat "$logfile"
First line
Another line
kschmidt      formatted line    7f
```

Create Files with `cat`

Editors

- `cat`, in the absence of command-line args, reads from `stdin`, writes to `stdout`
- We can use this to write to a file
 - Use `^D` (Ctrl-D) to end input

```
$ cat > "$ofile"  
This is line one  
Another line  
  
Okay, that's enough  
^D
```

- Handy way to concatenate files:

```
$ cat part1 > result  
$ cat part2 >> result
```

stderr is file descriptor 2, so:

```
$ gcc buggy.c 2> error.log  
$ grep '[Vv]era' *.html > results 2> error.log
```

To send both to the same place:

```
$ find . -name 'core*' > core.list 2>&1
```

- Note, the order matters
- Bash has syntactic sugar for this move:

```
$ find . -name 'core*' &> core.list
```

- `<` redirects `stdin` from a file
 - File descriptor 0

```
$ sort < nums
```

```
$ mail -s"Meaningful subject" $id < msg
```

- You can do both

```
$ sort < nums > sortednums 2> sort.errors
```

```
$ tr 'a-z' 'n-za-m' < code.rot13 > decoded
```

Here Documents/Strings

- *Here documents* are helpful in scripts
- Input is redirected using `« [-] WORD`
 - *WORD* signals end of input
- We'll examine these further in a subsequent lecture

```
$ cat << EOS
```

```
Dear $NAME:
```

```
I am writing this slowly, since I know you can't read fast.
```

```
It was so windy here Tuesday the chicken laid the same egg  
$EGG_CNT times.
```

```
EOS
```

- *Here strings* are convenient on the command line:

```
$ bc -l <<< "$x + s($d)"
```

*The use of pipes and other features to combine
“small, sharp tools” to accomplish larger tasks
– Ken Thompson (father of Unix)*

*“...at its heart is the idea that the power of a
system comes more from the relationship among
programs than from the programs themselves.”
– Brian Kernighan & Rob Pike*

*“This is the Unix philosophy: Write programs that
do one thing and do it well. **Write programs to
work together. Write programs to handle text
streams, because that is a universal interface.**”
– Doug McIlroy (inventor of the Unix pipe)*

Processes,
Jobs

Editors

- Processes are run in a subshell
- Subshells inherit exported environment
- Each process has an ID (PID) and a parent (PPID)
- Use the `ps` utility to look at processes:

```
$ ps
  PID TTY          TIME CMD
   350 pts/4    00:00:00 bash
 22251 pts/4    00:00:00 vim
 22300 pts/4    00:00:00 ps
```

- Use the `-f` option for a long (full) listing

```
$ ps -f
```

UID	PID	PPID	C	STIME	TTY	TIME	CMD
kschmidt	350	349	0	10:06	pts/4	00:00:00	-bash
kschmidt	22251	350	0	17:32	pts/4	00:00:00	vim myHomework
kschmidt	22437	350	0	17:36	pts/4	00:00:00	ps -f

- Use the `-e` option to see *all* of the processes (not just yours)

Editors

- The `kill` (built-in and utility) sends a signal to a process
 - By default, sends the `SIGTERM` (signal 15)
 - Send `SIGKILL` (9), won't be ignored, but, no cleanup
- To kill a process using its PID:

```
$ kill 29940
```

```
$ kill -n9 29940 # if it ignored your previous request
```

- See also `pgrep` and `pkill`

The shell allows you to manage jobs

- Place a job in the background
- Move a job to the foreground
- Suspend a job
- Kill a job
- Use `jobs` to view current jobs (in a given shell)

```
$ jobs
[2]  Running evince unix.pdf & (wd: ~/CS265/Lectures/Unix)
[4]  Running gimp & (wd: ~/public_html/CS265/Lectures/Unix)
[6]-  Running soffice CS265/Lectures/Unix/intro.ppt & (wd: ~)
[7]+  Stopped vi hello.tex
```

Processes,
Jobs

Editors

- When a process is running, the shell is blocked
- So, we run, e.g., GUI programs in the background
- Processes that might take a while we can place in the background
- Place a `&` after a command to run it in the background:

```
$ firefox &  
$ evince unix.pdf &  
$ find ~/ -type f -mtime -1 > find.out # this might run a while  
$ # Save output to a file
```

Suspending and Resuming a Process

Editors

- Use `^Z` to suspend the process in the foreground
- Use `fg` to bring the most recent process back to the foreground
 - Working in an editor, I'll save, `^Z` out, compile, then `fg` back to my editing session
- Or, type `%n`, where `n` is the index, from the `job` listing
- Use `bg` to put the most recently suspended process into the background

```
$ evince unix.pdf # Whoops! Forgot to put in background
^Z # Suspend evince
$ bg # Set it running in the background
```

Processes,
Jobs

Editors

- You can kill a job much as you might a process
- SIGTERM is often like closing the window, or choosing "Quit"
 - SIGKILL, on the other hand, can't actually be trapped
 - The plug will be pulled on the process, no chance to clean up
 - Not really nice
- Specify a job using %:

```
$ kill %4      # Give it a chance to exit itself
$ kill -n9 %4  # Just pull the plug
```

- In this course you will use either `emacs` or `vim`
- It is well worth learning a good, richly-featured editor
 - Syntax highlighting
 - Regular expression search and replace
 - Keyboard navigation
 - Extensible through macros
 - Much more
- GUI versions of `emacs` and `vim` exist
- Take the time to learn navigation, w/out the mouse and the arrows
 - You won't always have a GUI running
 - After a bit of practice, the mouse simply slows you down

emacs VS. vim

I, for good or ill, am a VI guy, so, I'll better be able to answer those questions

- `vim` – Vi IMproved

- Was the standard Unix editor

- Built on `ed`

- Shares some syntax with `sed`, and many other utilities, including, amusingly, `mutt` and `cmus`, my mp3 player

- `emacs` is written in (Emacs) LISP

- A bit more powerful than `vim` (you can run a shell inside, or, play Tetris)

- The default editor for Linux

Both are excellent text editors. Both have a steep-ish initial learning curve. Put in the time, learn one!
